Sample Animal Physiology Exam Questions with Answers

Question 1: Multiple Choice

Q: Which of the following hormones is primarily responsible for regulating blood calcium levels?

A) Insulin B) Parathyroid hormone C) Calcitonin D) Glucagon

Answer: B) Parathyroid hormone

Explanation: Parathyroid hormone (PTH) increases blood calcium levels by stimulating bone resorption, increasing intestinal calcium absorption, and reducing calcium excretion by the kidneys. Calcitonin, on the other hand, lowers blood calcium levels.

Question 2: Short Answer

Q: Describe the process of synaptic transmission across a neuron.

Answer: Synaptic transmission involves the transfer of nerve impulses from one neuron to another across a synapse. When an action potential reaches the presynaptic terminal, it triggers the opening of voltage-gated calcium channels. Calcium ions enter the neuron, prompting synaptic vesicles to fuse with the presynaptic membrane and release neurotransmitters into the synaptic cleft. These neurotransmitters bind to specific receptors on the postsynaptic neuron, leading to the opening of ion channels that generate a new action potential if the threshold is reached. The process is terminated by neurotransmitter reuptake, enzymatic degradation, or diffusion.

Question 3: Essay

Q: Explain the process of muscle contraction in vertebrates.

Answer: Muscle contraction in vertebrates occurs through the sliding filament mechanism, involving the interaction of actin and myosin filaments within muscle fibers. Upon stimulation by a nerve impulse, calcium ions are released from the sarcoplasmic reticulum into the cytoplasm. Calcium binds to troponin, causing a conformational change that moves tropomyosin away from the myosin-binding sites on actin filaments. This allows myosin heads, energized by ATP hydrolysis, to bind to actin forming cross-bridges. The myosin heads then pivot, pulling the actin filaments toward the center of the sarcomere—a process known as the power stroke. ATP binding to myosin causes detachment from actin, and the cycle repeats as long as calcium ions remain elevated. Relaxation occurs when calcium is pumped back into the sarcoplasmic reticulum, and the filaments slide back to their resting positions.

Question 4: Problem-Solving

Q: An animal consumes oxygen at a rate of 150 mL/min. If the animal's body weight is 10 kg, calculate its oxygen consumption per kg per hour.

Answer: First, convert oxygen consumption to per hour: $150 \text{ mL/min} \times 60 \text{ min} = 9000 \text{ mL/hour}$

Now, divide by body weight: $9000 \text{ mL/hour} \div 10 \text{ kg} = 900 \text{ mL/kg/hour}$

Final answer: The animal consumes 900 mL of oxygen per kilogram of body weight per hour.

QuestionAnswer

What are the primary functions of the circulatory system in animals?

The primary functions of the circulatory system in animals include transporting nutrients, oxygen, and hormones to cells, removing waste products, and maintaining homeostasis by regulating temperature and pH levels.

How do different animal species adapt their respiratory systems to their environments?

Animals adapt their respiratory systems based on their habitats; for example, aquatic animals like fish use gills for extracting oxygen from water, while terrestrial animals have lungs to breathe air. Some amphibians can also absorb oxygen through their skin, and certain species have specialized structures to survive in low-oxygen environments.

Explain the process of muscle contraction in animals.

Muscle contraction occurs when the nervous system stimulates muscle fibers, causing the release of calcium ions inside the muscle. This triggers the interaction between actin and myosin filaments, leading to the sliding filament mechanism that shortens the muscle and produces contraction.

What is the role of the kidneys in animal physiology?

The kidneys regulate water and electrolyte balance, remove waste products from the blood through filtration, and help control blood pressure. They also play a crucial role in maintaining acid-base balance and producing hormones such as erythropoietin.

Describe how thermoregulation is achieved in endothermic animals.

Endothermic animals maintain a stable internal body temperature through metabolic heat production and heat conservation mechanisms such as vasoconstriction, shivering, and behavioral adaptations like seeking shade or basking to dissipate or generate heat as needed.

What are the differences between the nervous and endocrine systems in animal physiology?

The nervous system provides rapid, short-term responses to stimuli through electrical signals and nerve impulses, while the endocrine system regulates longer-term processes via hormones released into the bloodstream, affecting various tissues and organs over time.
